This 30-year-old caucasian female presented to the office, having been referred for the treatment of tooth #8. The patient’s chief concern at the initial visit related to the tooth’s pink discoloration.

Upon clinical examination, it was discovered that tooth #8 had a previous history of trauma, and it was surmised that the clinical crown had become noticeably pink in color as a result of internal resorption (Fig. 1). This diagnosis was confirmed radiographically, indicating a large radiolucency involving the central and distal portions of the clinical crown (Fig. 2).

It was determined that restoration of this tooth was not possible, and therefore, extraction was indicated. The presence of a mid-line diastema, which the patient wanted to reproduce, directed the treatment plan for tooth replacement utilizing a dental implant.

Her medical and dental health, including a periodontal and occlusal analysis, identified her as a good candidate for dental implant surgery and restoration. Although she presented with a high lip line and a thin-gingival phenotype, an immediate placement technique with a conventional restorative loading protocol was recommended to accelerate her rehabilitation.

The clinical and radiological findings, in combination with the patient’s treatment expectations, led to an esthetic risk profile summing up to a medium esthetic risk, as per the specifications delineated by Martin et al 2007.

Prior to the initiation of the dental implant surgery, mounted diagnostic study casts were obtained and a surgical guide was fabricated.

The immediate implant surgical procedure for tooth #8 was carried out as described by Beagle 2006 (Figs. 3–7).

Excellent primary stability was obtained using a 12 mm 3.3-4.8 Regular Neck TE Straumann dental implant (Figs. 8, 9).

Fig. 1: Caucasian female, age 30, presents with internal resorption of tooth #8. A highly scalloped, thin type I gingival phenotype is clinically evident. (Photos/Provided by Dr. Jay R. Beagle)

Fig. 2: Periapical radiograph of teeth #8 and #9 illustrating the resorption defect associated with tooth #8.
Grafting of the horizontal defect dimension and thin labial plate was performed using autogenous bone and a resorbable collagen membrane (Figs. 10, 11).

A semi-submerged flap closure was chosen to enhance the final positioning of the peri-implant soft tissues, and a periapical radiograph was taken immediately following surgery (Figs. 12–14).

Ten weeks following implant surgery, a small gingivectomy was performed to gain access to the beveled healing cap (Figs. 15, 16).

A synOcta provisionalization coping was attached to the implant (Figs. 17, 18), and a self-curing acrylic resin provisional restoration was fabricated and marginated using a synOcta laboratory analog as described by Higginbottom and coworkers 2004 (Figs. 19, 20).
The peri-implant soft tissues were allowed to mature around the provisional restoration for four weeks prior to final impression (Figs. 21 – 23). Following connection of the analog to the impression coping, a master cast was fabricated to reproduce the implant location three-dimensionally. The master cast was then utilized to aid in the creation of a screw-retained cast-metal crown framework using an autogenous bone graft into the horizontal defect dimension (HDD) along the buccal surface.

a non-rotational synOcta gold coping. Following the insertion of a 1.5 synOcta abutment (Fig 26), which was hand tightened, the crown framework was attached to the implant with an SCS occlusal screw, and a second definitive impression using a closed tray technique was made to verify the peri-implant soft tissue profiles (Figs. 27–30).

The ceramic work was completed at the laboratory using this accurate master cast. The 1.5 synOcta abutment was torqued to 35 n/cm² and the final
crown was seated and checked for marginal fit, occlusal and interproximal contacts and emergence profile (Fig. 31).

Final glazing of the ceramics was then performed, and the SCS occlusal screw was tightened to 15 n/cm². The screw access was obturated with a cotton pledget and restored with a light cured composite (Fig. 32).

A periapical radiograph was obtained to establish a baseline marginal bone level with maintenance of the implant (Figs. 33, 34).
visits scheduled every six months with the dental hygienist (Figs. 33, 34).

The one-year follow-up showed an excellent result clinically and radiographically with very stable peri-implant soft tissues and optimal crestal bone heights (Fig. 35).

Acknowledgments

Prosthetic procedures: Dr. Richard Stuart, private practice, Indianapolis, Ind.

Laboratory procedures: Michael Hahn, Boca Raton, Fla.

Jay R. Beagle has recently published ‘Surgical Essentials of Immediate Implant Dentistry’ with a foreword by David L. Cochran.

‘Surgical Essentials of Immediate Implant Dentistry’ provides a complete text on this important treatment modality. Assisting readers to make sense of the various clinical techniques and protocols, Beagle discusses the available underlying evidence to provide a practical, comprehensive and navigable aid to attaining a thorough understanding of this complex and highly relevant subject.

Dr. Jay R. Beagle is a fellow of the ITI and a leader in the fields of periodontics and dental implant surgery. Trained at the Indiana University School of Dentistry, Beagle received his periodontal certificate and master’s degree from the University of Kentucky. He remains at the forefront of implant dentistry research, development and education, most notably in the areas of immediate placement and anterior esthetics. Beagle has lectured extensively both nationally and internationally, including presentations at ITI World Symposia, the American Academy of Periodontology, the Academy of Osseointegration and the European Academy of Osseointegration. Devoted to education, Beagle has published a textbook, co-authored numerous articles and a surgical training CD-ROM, and he participates in numerous national and international committees and consensus conferences. He is actively involved with clinical dental research, with several clinical research projects continually in progress.

Beagle maintains a private practice in Indianapolis, Ind., limited to periodontics and dental implant surgery.
